

# Water budgets of the two Olentangy River experimental wetlands in 2000

Li Zhang and William J. Mitsch

*School of Natural Resources, The Ohio State University*

## Introduction

Hydrologic conditions are extremely important for the maintenance of wetland structure and function. Biota, water quality and vegetation dynamic determine a wetland's overall water budget (Mitsch and Gosselink, 2000). Since 1994, a combination of manual and automated observations has provided a wealth of information on the daily, and even hourly, water fluxes of the two experimental wetlands at the Olentangy River Wetland Research Park (ORWRP). Annual water budgets at the ORWRP were presented by Mitsch (1995), Wu et al. (1995), Nairn et al. (1996), Wang et al. (1997), Wang et al. (1998), Wang and Mitsch (1999) and Zhang et al. (2000). These reports, provide estimates of daily water fluxes and flooding events of the two Olentangy River experimental wetlands for each year. As part of a

long-term wetland ecosystem study (Mitsch, 2000), the water budget for 2000 is part of this research. To allow water budgets to be compiled on a consistent basis, there is a need to follow previous procedures and modeling approaches while integrating observations, in part because of the very abundance of data and also because of the periodic occurrence of atypical events such as floods and equipment malfunctions. These procedures were used as a model in developing the 2000 wetland water budgets.

## Methods

Locations of the inflow and outflow reading are shown in Figure 1. The following general equation (Mitsch and Gosselink, 1993) was used to determine a water budget for each ORWRP experimental wetland:

Figure 1. Location of pumped inflow and outflow of Wetland 1 and Wetland 2 at ORWRP. Hydrologic sampling stations are marked and the inflow of Wetland 1 is shown on the right.

$$S_i + F_i + P - S_o - ET - G_o - \Delta V = 0 \quad (1)$$

where,

$S_i$  = pumped inflow (surface)

$F_i$  = flood inflow (due to floods on the Olentangy River)

$P$  = precipitation

$S_o$  = surface outflow

$ET$  = evapotranspiration

$G_o$  = ground water outflow (seepage)

$\Delta V$  = change in volume

All parameters were developed in equivalent units for a budget calculation; either average flow rate (i.e., gpm) over a given time period, or total depth (i.e., cm) over a given time period, where total area was taken as a nominal 10,000 m<sup>3</sup> (1 ha) for each wetland.

A 4-hour time increment was used as the basis for computing all parameters in 2000. However, the budget is reported only for daily values.

### *Pumped Inflow ( $S_i$ )*

Twice-daily (morning and evening) readings of both instantaneous and total integrated volume of pumping rates were collected by staff and students from the flow monitors in each pipe going to each wetland. Many gaps have continued to exist in the data when flow gauges clogged or when readings were missed. When data from only one wetland inflow were available, the missing flow rate was assumed to be the same as the available flow rate (the protocol for the experimental wetlands has been, since the start, to deliver the same flow to each wetland at all times). When both flow gauges were malfunctioning, flow was estimated for both from the best estimate of previous readings or from pump settings (number of turns open). When pumps were shut down, either by site managers or by accident, the time of shutdown was estimated from field records and flow was prorated for only the period when pumps were not operating.

For the 2000 budget, readings from the inflow meters were interpolated to determine 4-hour total flow increments, in gallons, for each wetland. Water level recorder data charts, when available, were used to determine exact times of power outages or other unusual occurrences.

### *Flood Inflow ( $F_i$ )*

There was no surface flood in the experimental basins in 2000, though there was a high river staff gauge reading (18.70 feet on Apr. 8 at 16:45 pm).

### *Precipitation ( $P$ )*

Precipitation was measured on half-hour frequency with a Unidata Model 6506B tipping bucket rain gauge located in the on-site meteorological station located between the two experimental wetlands. When the gauge was not working during winter, precipitation data were obtained from two-per-day site monitorings of 3 precipitation gages that were emptied after each recording or from liquid precipitation

data from the OSU Agronomy Farm weather station, located 1 km from the ORWRP. The half-hourly precipitation data from the on-site weather station were used to derive 4-hour precipitation totals. Liquid precipitation in the form of snow was not easily accounted for during winter.

### *Surface Outflow ( $S_o$ )*

Outflow measurements from the experimental wetlands are based on wetland water level and the status of the control weir boxes constructed at the southern edge of the basins (Figure 2). The three important variables needed are: 1) the water level in the basins; 2) the status of weirs or other control devices in the weir boxes; and 3) the crest elevation of the weir or other control device. These data are then used with weir equations that relate head to rate of outflow. When outflow was blocked with debris, outflow was estimated from equation 1.

### *Wetland Water Level*

From the beginning of the project, water level has been recorded twice-per-day by reading a staff gauge located near the outflow. Figure 2 shows staff gauge and outflow outlet for Wetland 1. Beginning in early 1996, water level was continuously recorded by Stevens Type F water level recorders located in the southernmost deep pool of each wetland and accessible by boardwalk. Recordings were set to 1:1 scale and charts were changed weekly. Water levels were graphically determined from chart records at 4-hour intervals.

Figure 2. Staff gauge and outflow weir box of Wetland 1.

### Weir Box Status

Four different conditions of weir box outflow control have occurred since 1995: v-notch plate in place (V+0); v-notch and one stoplog in place (V+1); v-notch and two stoplogs in place (V+2); and no v-notch or stoplog (noweir). Details of computing outflow with v-notch were given in Wang and Mitsch (1999). Major hydrological events are presented in Table 1. No weir plate was in place for Wetlands 1 and 2 in 2000.

### Flow Equations with No Weir

Rating curves developed from velocity readings in the outflow pipes downstream of the weirs were used to estimate outflow. These empirical equations are:

$$\text{for Wetland 1: } S_o = 0.310 H^{3.490} \quad (2)$$

$$\text{for Wetland 2: } S_o = 0.467 H^{2.747} \quad (3)$$

where

$S_o$  = outflow, cfs,

$H$  = head, feet

The head here is the elevation above the bottom of the empty weir box.

### Evapotranspiration (ET)

For 2000, pan evaporation data from the on-site weather station were used and corrected using a factor of 0.75.

Table 1. Major hydrology events affecting ORWRP hydrology during the year 2000.

### Seepage to Ground Water ( $G_o$ )

Changes in wetland volume during these periods that were not accounted for by precipitation or evapotranspiration could be used to estimate seepage, as follows:

$$G_o = -\Delta V + P - ET \quad (4)$$

Time periods during which the no-inflow/no-outflow criteria were satisfied (see Appendix A) occurred when pumps were shut down, either for drawdown or for maintenance reasons, and wetland water levels were below the weir. However, no such periods were observed during 2000. Residual in the water budget was treated as seepage to ground water.

### Change in Volume ( $\Delta V$ )

Net change in wetland volume over any given period was determined using beginning and ending water levels

and the known relationship between water levels and wetland volume. Net change was calculated from charts on a four-hour basis and used to calculate the water budget.

## Results and Discussion

Figures 3 and 4 show pumped inflows and water levels of both Wetland 1 and Wetland 2 in 2000. Annual and monthly hydrologic budgets were summarized for 2000 (Table 2). In 2000, inflows to Wetlands 1 and 2 were 32.1 m and 31.9 m, respectively. Surface outflow for 2000 was estimated to be 29.4 m for each wetland, approximately 91% and 92% of pumped inflow. Daily flows on which these budgets were based are attached in Appendix A. Highest daily pumped values were 660 gpm and 747 gpm on Jan. 4, 2000 for Wetland 1 (W1) and Wetland 2 (W2), respectively. Figure 5 shows cumulative daily outflow vs cumulative daily inflow of the two Olentangy River experimental wetlands in 2000. The average retention time
